Abstract

This paper presents a typed higher-order concurrent functional programming language, based on Moggi's monadic metalanguage and Reppy's Concurrent ML. We present an operational semantics for the language, and show that a higher-order variant of the traces model is fully abstract for may-testing. This proof uses a program logic based on Hennessy–Milner logic and Abramsky's domain theory in logical form.

1 Introduction

This paper presents an operational semantics for a concurrent functional programming language, based on Reppy's [26, 27] Concurrent ML, and Moggi's [22] monadic metalanguage.

CML is a concurrent extension of New Jersey ML, which adds communication primitives based on CCS [19] and CSP [11]. Reppy introduces a new type constructor of *events*, which can spawn concurrent processes, and communicate with them along channels.

Three of the constructors for the event type are:

$$\begin{aligned} \text{always} &: \alpha \rightarrow \alpha \text{event} \\ \text{wrap} &: (\alpha \text{event} \times \alpha \rightarrow \beta) \rightarrow (\beta \text{event}) \\ \text{sync} &: \alpha \text{event} \rightarrow \alpha \end{aligned}$$

These are:

- `always e` is an event which always returns e ,
- `wrap(e, f)` is an event which evaluates e and applies f to the result, and
- `sync e` starts the evaluation of a event.

Moggi has proposed a more radical type system for computation, where *all* computation is indicated in the type system by a type constructor, here denoted C . So whereas `nat` in Moggi's setting is a type whose expressions are integers, $C \text{ nat}$ is a type whose expressions are computations of integers. For example, `37` is of type `nat` where `37 + 52` is of type $C \text{ nat}$.

Moggi has shown that a simple programming language called the monadic metalanguage, equipped with certain equations forms a *strong monad* [16, for example], that is

a category \mathbf{C} with a functor $T : \mathbf{C} \rightarrow \mathbf{C}$ with natural transformations:

$$\begin{aligned} \eta_X &: X \rightarrow TX \\ \mu_X &: T^2X \rightarrow TX \\ t_{X,Y} &: X \times TY \rightarrow T(X \times Y) \end{aligned}$$

subject to certain commuting diagrams. There is a close correspondence between Reppy's operators for CML and the structure of a monad:

<i>CML gadget</i>	<i>Monadic gadget</i>
<code>event</code>	T on objects
<code>wrap</code>	T on arrows
<code>always</code>	η
<code>sync</code>	μ
<code>$\lambda(x,y). \text{wrap}(y, \lambda z. (x,z))$</code>	t

In this paper, we shall show how the practice of CML and the theory of MML can be brought together. We present a concurrent programming language CMML whose type system is based on MML, and whose concurrent features are based on a subset of CMML. We present an operational and denotational semantics for CMML, and show that the denotational semantics is fully abstract.

The new results of this paper are:

- Applying Moggi's theory in an operational, rather than denotational, setting. Moggi has concentrated on the equational and denotational semantics for MML, for example expressing nondeterminism as powerdomain rather than operationally. The use of monads in lazy functional programming, pioneered by Wadler [31] and since used in specifying IO [6, 7] for Haskell [14] has concentrated on the algebraic properties of computation types.
- Providing an operational semantics for a CML-like language in the form of a labelled transition system. Reppy's operational semantics for CML uses a reduction system more like Standard ML [21] than CCS.
- Giving a fully abstract semantics for a typed higher-order concurrent language. Hennessy [10] has proved

full abstraction for untyped higher-order processes, and there has been much work on translating higher-order languages like CHOCS [29, 30] or Facile [4, 28] into basic languages like the π -calculus [20]. Bolignano and Debabi [5] have presented an operational and denotational semantics, which is more complex than that given here, but do not have a full abstraction result.

This paper is an extended abstract of part of [15]. That paper also contains foundational material on the categorical structure formed by various algebras of programming languages, and a translation of a subset of CML into CMML, which is correct up to weak bisimulation. All proofs are only given in sketch form, and are detailed in the full paper.

2 Syntax

The language we shall consider in this paper is a typed functional programming language with concurrent and nondeterministic features.

The type system is based on MML, and includes a computation type constructor $C\tau$.

The communication mechanism is based on CML, however, our treatment is missing a number of features, most importantly dynamic channel creation. This is allowed in CML, and is addressed operationally in languages such as Milner, Parrow and Walker's [20] π -calculus, and Thomsen's [29, 30] CHOCS. Pitts and Stark [24] have investigated denotational models of such languages, but there is not (yet) a fully abstract model for such languages in **Alg** or a similar category of domains. Since we are interested in showing fully abstraction for the traces semantics, we shall not attempt a treatment dynamic name creation for the moment.

A signature with *booleans, channels and destructors* is a signature with:

- a set of *sorts* ranged over by A, B , and C ,
- a set of *constructors* ranged over by c , with sorting $c : A_1, \dots, A_n \rightarrow B$,
- a set of *destructors* ranged over by d , with sorting $d : A_1, \dots, A_n \rightarrow B$,
- a sort `bool` with constructors `true, false` : $\rightarrow \text{chan}$, and
- a sort `chan` with destructor `eq` : `chan, chan` $\rightarrow \text{bool}$ such that the term algebra for `chan` is countably infinite.

a sort `chan` such For example, we can define a signature `NatList` with sorts:

`bool` `nat` `list`

constructors:

`true, false` : $\rightarrow \text{bool}$
`zero` : $\rightarrow \text{nat}$
`succ` : `nat` $\rightarrow \text{nat}$
`nil` : $\rightarrow \text{list}$
`cons` : `nat, list` $\rightarrow \text{list}$

and destructors:

`eq` : `nat, nat` $\rightarrow \text{bool}$
`pred` : `nat` $\rightarrow \text{nat}$
`isnil` : `list` $\rightarrow \text{bool}$
`hd` : `list` $\rightarrow \text{nat}$
`tl` : `list` $\rightarrow \text{list}$

and we can use `nat` as the sort of channels.

Let **SigBCD** be the category of signatures with booleans, channels and destructors, together with morphisms which respect the booleans, channels, and sorting of constructors and destructors.

Given a signature with booleans, channels and destructors Σ , we can define the language $\text{CMML}\Sigma$ to be the *concurrent monadic metalanguage* over Σ given by the grammar:

$$e ::= * \mid c(e_1, \dots, e_n) \mid d(e_1, \dots, e_n) \mid (e, e) \mid v$$

$$\mid [e] \mid \text{let } x \leftarrow e \text{ in } e \mid \lambda x. e \mid ee \mid \text{if } e \text{ then } e \text{ else } e$$

$$\mid \delta \mid e \square e \mid \text{fix}(x = e) \mid e!_{\tau} e \mid e?_{\tau} \mid e \parallel e \mid e \dot{\mid} \bar{e}$$

$$v ::= x \mid v.L \mid v.R$$

where x ranges over a set of *variables*. We shall call expressions v *lvalues*. These expressions are:

- $*$ is the only closed term of unit type.
- $c(\bar{e})$ is the application of a constructor, to build a value of base type.
- $d(\bar{e})$ is the application of a destructor, to build a computation of base type.
- (e, f) is pairing.
- $v.L$ and $v.R$ are the left and right projections. We shall see later that restricting projections to *lvalues* allows us to know the syntactic form of terms from just the type information.
- $[e]$ is a computation which immediately terminates with result e . This is similar to 'exit' in LOTOS [1], and 'return' in CML.
- $\text{let } x \leftarrow e \text{ in } f$ is a computation which evaluates e until it returns a value, which is then bound to x in f . For example, $\text{let } x \leftarrow [\text{zero}] \text{ in } [\text{succ}.x]$ is the same as $[\text{succ}.\text{zero}]$.
- $\lambda x. e$ is function binding.
- ef is function application.
- δ is a deadlocked term, which has no reductions.
- $e \square f$ gives the external choice between e and f . This is similar to CSP's external choice, and CML's 'choose'.
- $\text{fix}(x = e)$ gives the fixed point of e at x .
- $e!_{\tau} f$ outputs the expression f of type τ along channel e and then returns $*$. This is similar to CML's 'send'.
- $e?_{\tau}$ inputs any expression f of type τ along channel e and then returns f . This is similar to CML's 'accept'.
- $e \parallel f$ performs e and f in parallel, allowing them to communicate. It will return any value that f returns. This can be defined in terms of CML's 'spawn'.

- $e \upharpoonright f_1, \dots, f_n$ behaves like e but can only communicate on the channels f_i . This is similar to SCCS's [18] restriction, but does not have an analogue in CML, where channel scope is treated as in the π -calculus.

We can give CMML Σ a static type system, with types:

$$\tau ::= I \mid [A] \mid \tau \otimes \tau \mid C\tau \mid \tau \rightarrow C\tau$$

These types are:

- I is the unit type, whose only closed term is $*$,
- $\sigma \otimes \tau$ is the type of pairs of σ and τ ,
- $[A]$ is a base type taken from Σ ,
- $C\tau$ is a computation, which returns an expression of type τ , and
- $\sigma \rightarrow C\tau$ is a function, which when applied to an expression of type σ returns an expression of type $C\tau$.

The type judgements for CMML are of the form $\Gamma \vdash e : \tau$ given by rules in Table 1, where Γ ranges over *contexts* of the form $x_1 : \tau_1, \dots, x_n : \tau_n$.

For example, `succzero` is an expression of type $[\text{nat}]$, whereas `pred(succzero)` is an expression of type $C[\text{nat}]$. This corresponds to the intuition that whereas 1 is *data*, and can be stored in an implementation as a bit string, $1 - 1$ is *computation*, and has to be stored as a pointer to code (until it is evaluated, at which point the result `zero` is of type $[\text{nat}]$).

Moggi has shown how the call-by-value λ -calculus can be translated into the monadic metalanguage, and the full version of this paper contains a translation of a subset of CML into CMML, which is correct up to weak bisimulation.

Note that we are only allowing functions to return computations, for example there is no type $I \rightarrow I$, only $I \rightarrow CI$. This corresponds to our intuition that the only terms which involve computation are terms of type $C\tau$, and this would not be true if we allowed functions to return arbitrary type.

This restriction, coupled with the restriction of projections $v.L$ and $v.R$ to lvalues allows us to show that:

- any term of type I is either an lvalue or $*$,
- any term of type $[A]$ is either an lvalue or of the form $c(e_1, \dots, e_n)$,
- any term of type $\sigma \otimes \tau$ is either an lvalue or of the form (e, f) , and
- any term of type $\sigma \rightarrow C\tau$ is either an lvalue or of the form $\lambda x. e$.

In particular, the only closed terms of type $[A]$ are taken from the term algebra for Σ , so CMML Σ is a conservative extension of the term algebra for Σ .

We have only defined projections on lvalues, however we know that any term $\Gamma \vdash e : \sigma \otimes \tau$ is either a pair or an lvalue, and so we can define $\Gamma \vdash \pi e : \sigma, \pi' e : \tau$ as syntactic sugar:

$$\begin{aligned} \pi v &= v.L & \pi(e, f) &= e \\ \pi' v &= v.R & \pi'(e, f) &= f \end{aligned}$$

We can use this to define substitution $e[f/x]$ in the normal fashion, except that we substitute for lvalues as:

$$(v.L)[f/x] = \pi(v[f/x]) \quad (v.R)[f/x] = \pi'(v[f/x])$$

We have only defined recursion on computations rather than on functions. However, we can define recursive functions as syntactic sugar:

$$\text{fix}(x = \lambda y. e) = [\text{fix}(z = (\lambda x. [\lambda y. e])[z])]$$

where:

$$[e] = \lambda y. \text{let } x \Leftarrow e \text{ in } xy$$

These have typing:

$$\frac{\Gamma \vdash e : C(\sigma \rightarrow C\tau)}{\Gamma \vdash [e] : \sigma \rightarrow C\tau} \quad \frac{\Gamma, x : \sigma \rightarrow C\tau, y : \sigma \vdash e : C\tau}{\Gamma \vdash \text{fix}(x = \lambda y. e) : \sigma \rightarrow C\tau}$$

We can also write $\lambda(\vec{x}). e$ as syntactic sugar, for example:

$$\lambda(x, y). e = \lambda z. e[z.L/x, z.R/y]$$

For example, a recursive function to add an element to the end of a list is:

$$\begin{aligned} \text{snoc} &: [\text{list}] \otimes [\text{nat}] \rightarrow C[\text{list}] \\ \text{snoc} &= \text{fix}(u = \lambda(v, w). \text{let } x \Leftarrow \text{isnil } v \text{ in} \\ &\quad \text{if } x \\ &\quad \text{then } [\text{cons}(w, \text{nil})] \\ &\quad \text{else let } y \Leftarrow \text{hd}(v) \text{ in} \\ &\quad \quad \text{let } y' \Leftarrow \text{tl}(v) \text{ in} \\ &\quad \quad \text{let } z \Leftarrow v(y', w) \text{ in} \\ &\quad \quad [\text{cons}(y, z)]) \end{aligned}$$

and an unbounded buffer can be defined by maintaining a list of elements:

$$\begin{aligned} \text{buff} &: [\text{chan}] \otimes [\text{chan}] \otimes [\text{list}] \rightarrow C\tau \\ \text{buff} &= \text{fix}(u = \lambda(x, y, z). \text{let } w \Leftarrow x?_{\text{nat}} \text{ in} \\ &\quad \text{let } z \Leftarrow \text{snoc}(z, w) \text{ in} \\ &\quad u(x, y, z) \\ &\quad \square \text{let } w \Leftarrow \text{hd } z \text{ in} \\ &\quad \quad \text{let } v \Leftarrow y!_{\text{nat}} w \text{ in} \\ &\quad \quad \text{let } z \Leftarrow \text{tl } z \text{ in} \\ &\quad \quad u(x, y, z)) \end{aligned}$$

Note that programs in CMML are often more verbose than in CML, due to the number of `let` statements required. This is the cost of making the evaluation order syntactically explicit, rather than implicit as in ML.

3 Operational semantics

In this section we define the operational semantics of CMML Σ . This is given as a *higher-order symbolic value production system*, that is:

$$\begin{array}{c}
\frac{}{\Gamma \vdash * : I} \quad \frac{\Gamma \vdash e : \sigma \quad \Gamma \vdash f : \tau}{\Gamma \vdash (e, f) : \sigma \otimes \tau} \\
\frac{\Gamma \vdash e_1 : [A_1] \quad \cdots \quad \Gamma \vdash e_n : [A_n]}{\Gamma \vdash c(e_1, \dots, e_n) : [A]} [c : A_1, \dots, A_n \rightarrow A] \quad \frac{\Gamma \vdash e_1 : [A_1] \quad \cdots \quad \Gamma \vdash e_n : [A_n]}{\Gamma \vdash d(e_1, \dots, e_n) : C[A]} [d : A_1, \dots, A_n \rightarrow A] \\
\frac{\Gamma \vdash v : (\sigma \otimes \tau)}{\Gamma \vdash v.L : \sigma} \quad \frac{\Gamma \vdash v : (\sigma \otimes \tau)}{\Gamma \vdash v.R : \tau} \quad \frac{}{\Gamma, x : \sigma \vdash x : \sigma} \quad \frac{\Gamma \vdash y : \tau}{\Gamma, x : \sigma \vdash y : \tau} [x \neq y] \\
\frac{\Gamma \vdash e : \tau}{\Gamma \vdash [e] : C\tau} \quad \frac{\Gamma \vdash e : C\sigma \quad \Gamma, x : \sigma \vdash f : C\tau}{\Gamma \vdash \text{let } x \leftarrow e \text{ in } f : C\tau} \quad \frac{\Gamma, x : \sigma \vdash e : C\tau}{\Gamma \vdash \lambda x. e : \sigma \rightarrow C\tau} \quad \frac{\Gamma \vdash e : \sigma \rightarrow C\tau, f : \sigma}{\Gamma \vdash e f : C\tau} \\
\frac{\Gamma \vdash e : [\text{bool}]}{\Gamma \vdash \text{if } e \text{ then } f \text{ else } g : C\tau} \quad \frac{\Gamma \vdash f : C\tau \quad \Gamma \vdash g : C\tau}{\Gamma \vdash \delta : C\tau} \quad \frac{\Gamma \vdash e : C\tau \quad \Gamma \vdash f : C\tau}{\Gamma \vdash e \square f : C\tau} \quad \frac{\Gamma, x : C\tau \vdash e : C\tau}{\Gamma \vdash \text{fix}(x = e) : C\tau} \\
\frac{\Gamma \vdash e : [\text{chan}], f : \tau}{\Gamma \vdash e!_{\tau} f : C I} \quad \frac{\Gamma \vdash e : [\text{chan}]}{\Gamma \vdash e?_{\tau} : C\tau} \quad \frac{\Gamma \vdash e : C\sigma, f : C\tau}{\Gamma \vdash e \parallel f : C\tau} \quad \frac{\Gamma \vdash e : C\tau, f_1 : [\text{chan}], \dots, f_n : [\text{chan}]}{\Gamma \vdash e \mid f_1, \dots, f_n : C\tau}
\end{array}$$

Table 1: Typing rules for CMMLΣ

- an *internal transition* relation $e \xrightarrow{\cdot} e'$,
- a *termination* relation $e \xrightarrow{\sqrt{\delta}} e'$,
- an *output* relation $e \xrightarrow{f!_{\sigma} g} e'$,
- an *input* relation $e \xrightarrow{f?_{\sigma} x} e'$, and
- a *deadlocked* term δ ,

with the typing:

- if $e \xrightarrow{\cdot} e'$ then $\vdash e : C\tau$ and $\vdash e' : C\tau$,
- if $e \xrightarrow{\sqrt{f}} e'$ then $\vdash e : C\tau$, $\vdash f : \tau$, and $\vdash e' : C\tau$,
- if $e \xrightarrow{f!_{\sigma} g} e'$ then $\vdash e : C\tau$, $\vdash f : [\text{chan}]$, $\vdash g : \sigma$, and $\vdash e' : C\tau$, and
- if $e \xrightarrow{f?_{\sigma} x} e'$ then $\vdash e : C\tau$, $\vdash f : [\text{chan}]$, and $x : \sigma \vdash e' : C\tau$,

where δ has no reductions, and where $\xrightarrow{\sqrt{f}}$ has the properties:

- if $e \xrightarrow{\sqrt{f}} e'$ then $e' \not\xrightarrow{\sqrt{g}}$,
- if $e \xrightarrow{\sqrt{f}} e'$ then $e \xrightarrow{\mu} e'$ then $e \xrightarrow{\mu} \sqrt{f} e'$, and
- if $e \xrightarrow{\sqrt{f}} e'$ and $e \xrightarrow{\mu} e''$ are distinct transitions, then $e' \xrightarrow{\mu} e'''$ and $e'' \xrightarrow{\sqrt{f}} e'''$ for some e''' ,

where we write $e \xrightarrow{\mu} e'$ for the *early* operational semantics given by:

- $e \xrightarrow{\cdot} e'$ iff $e \xrightarrow{\cdot} e'$,
- $e \xrightarrow{\sqrt{f}} e'$ iff $e \xrightarrow{\sqrt{f}} e'$,
- $e \xrightarrow{f!_{\tau} f'} e'$ iff $e \xrightarrow{f!_{\tau} f'} e'$, and
- $e \xrightarrow{f?_{\tau} f'} e'[f'/x]$ iff $e \xrightarrow{f?_{\tau} f'} e'$.

Let a range over visible actions $e!_{\tau} f$ and $e?_{\tau} x$, let α range over a and \cdot , and let μ range over all actions.

We can define an operational semantics for terms of the form $d\vec{e}$ or δ , such that the reductions of eq are (when $e \neq f$):

$$\text{eq}(e, e) \xrightarrow{\sqrt{\text{true}}} \delta \quad \text{eq}(e, f) \xrightarrow{\sqrt{\text{false}}} \delta$$

For example, the operational semantics for NatList is:

$$\begin{array}{ll}
\text{eq}(e, e) \xrightarrow{\sqrt{\text{true}}} \delta & \text{eq}(e, f) \xrightarrow{\sqrt{\text{false}}} \delta \\
\text{isnil}(\text{nil}) \xrightarrow{\sqrt{\text{true}}} \delta & \text{isnil}(\text{cons}(e, f)) \xrightarrow{\sqrt{\text{false}}} \delta \\
\text{hd}(\text{cons}(e, f)) \xrightarrow{\sqrt{e}} \delta & \text{tl}(\text{cons}(e, f)) \xrightarrow{\sqrt{f}} \delta \\
& \text{pred}(\text{succe}) \xrightarrow{\sqrt{e}} \delta
\end{array}$$

Note that we have not given any reductions for predzero, hd nil or tl nil, and so they deadlock.

Given a higher-order symbolic vps for terms of the form $d\vec{e}$ and δ , we can extend it to CMMLΣ as in Table 2.

Write $e \xrightarrow{\mu} e'$ for $e \xRightarrow{\mu} e'$, and $e \xrightarrow{\hat{\mu}} e'$ for $e \xRightarrow{\mu} e'$ or $e = e'$ and $\mu = \cdot$.

For example, one reduction of the buffer buff(i, o, nil) is:

$$\begin{array}{l}
\text{buff}(i, o, \text{nil}) \\
\Rightarrow \text{let } w \leftarrow i?_{\text{nat}} \text{ in} \\
\quad \text{let } z \leftarrow \text{snoc}(\text{nil}, w) \text{ in} \\
\quad \text{buff}(i, o, z) \\
\quad \square \text{let } w \leftarrow \text{hd nil in} \\
\quad \quad \text{let } v \leftarrow o!_{\text{nat}} w \text{ in} \\
\quad \quad \text{let } z \leftarrow \text{tl nil in} \\
\quad \quad \text{buff}(i, o, z) \\
\overset{i?n}{\Rightarrow} \text{let } w \leftarrow [n] \text{ in} \\
\quad \text{let } z \leftarrow \text{snoc}(\text{nil}, w) \text{ in} \\
\quad \text{buff}(i, o, z) \\
\overset{\cdot}{\Rightarrow} \text{let } z \leftarrow \text{snoc}(\text{nil}, n) \text{ in} \\
\quad \text{buff}(i, o, z) \\
\Rightarrow \text{buff}(i, o, \text{cons}(n, \text{nil}))
\end{array}$$

$$\begin{array}{c}
\frac{e \xrightarrow{\alpha} e'}{\text{let } x \leftarrow e \text{ in } f \xrightarrow{\alpha} \text{let } x \leftarrow e' \text{ in } f} \quad \frac{e \xrightarrow{\sqrt{g}} e'}{\text{let } x \leftarrow e \text{ in } f \xrightarrow{\sqrt{g}} \text{let } x \leftarrow e' \text{ in } f} \quad \frac{e \xrightarrow{\sqrt{e}} \delta}{(\lambda x. e) f \xrightarrow{\sqrt{e}} e[f/x]} \\
\frac{e \xrightarrow{\alpha} e'}{\text{fix}(x = e) \xrightarrow{\alpha} e[\text{fix}(x = e)/x]} \quad \frac{e \xrightarrow{a} e'}{\text{if true}() \text{ then } f \text{ else } g \xrightarrow{a} f} \quad \frac{e \xrightarrow{\sqrt{g}} e'}{\text{if false}() \text{ then } f \text{ else } g \xrightarrow{\sqrt{g}} g} \\
\frac{e \xrightarrow{\alpha} e'}{e \square f \xrightarrow{\alpha} e' \square f} \quad \frac{e \xrightarrow{a} e'}{e \square f \xrightarrow{a} e' \square f} \quad \frac{e \xrightarrow{\sqrt{g}} e'}{e \square f \xrightarrow{\sqrt{g}} e' \square f} \quad \frac{f \xrightarrow{\alpha} f'}{e \square f \xrightarrow{\alpha} e \square f'} \quad \frac{f \xrightarrow{a} f'}{e \square f \xrightarrow{a} e \square f'} \quad \frac{f \xrightarrow{\sqrt{g}} f'}{e \square f \xrightarrow{\sqrt{g}} e \square f'} \\
\frac{e \xrightarrow{\alpha} e'}{e \parallel f \xrightarrow{\alpha} e' \parallel f} \quad \frac{e \xrightarrow{g^! \tau h} e' \quad f \xrightarrow{g^? \tau x} f'}{e \parallel f \xrightarrow{\alpha} e' \parallel f[h/x]} \quad \frac{f \xrightarrow{\mu} f'}{e \parallel f \xrightarrow{\mu} e \parallel f'} \quad \frac{e \xrightarrow{g^? \tau x} e' \quad f \xrightarrow{g^! \tau h} f'}{e \parallel f \xrightarrow{\alpha} e' \parallel f[h/x]} \\
\frac{e \xrightarrow{\alpha} e'}{e \uparrow \vec{f} \xrightarrow{\alpha} e' \uparrow \vec{f}} \quad \frac{e \xrightarrow{\sqrt{g}} e'}{e \uparrow \vec{f} \xrightarrow{\sqrt{g}} e' \uparrow \vec{f}} \quad \frac{e \xrightarrow{f^? x} e'}{e \uparrow \vec{f}, f, \vec{f}' \xrightarrow{f^? \tau x} e' \uparrow \vec{f}, f, \vec{f}'} \quad \frac{e \xrightarrow{f^! g} e'}{e \uparrow \vec{f}, f, \vec{f}' \xrightarrow{f^! \tau g} e' \uparrow \vec{f}, f, \vec{f}'}
\end{array}$$

Table 2: Operational semantics for CMML Σ

---	---	--

A *bisimulation* is a simulation whose inverse is also a simulation. Then define:

- *simulation preorder* \preceq is the largest simulation,
- *mutual simulation equivalence* \asymp is $\preceq \cap \succeq$.
- *bisimulation equivalence* \approx is the largest bisimulation.

Given a type-indexed relation \mathcal{R}_τ of closed terms, let $\mathcal{R}_{\Gamma, \tau}^\circ$ be the corresponding relation on open terms:

$$\mathcal{R}_{\vec{x}; \vec{\sigma}; \tau}^\circ = \{(e, f) \mid \forall \vec{g} : \vec{\sigma}. e[\vec{g}/\vec{x}] = f[\vec{g}/\vec{x}]\}$$

We shall often elide the indexes from these relations, writing $e \mathcal{R} f$ rather than $e \mathcal{R}_\tau f$ and $e \mathcal{R}^\circ f$ for $e \mathcal{R}_{\Gamma, \tau}^\circ f$ when context makes the typing obvious.

Note that bisimulation is strictly finer than mutual simulation, for example:

$$\begin{aligned}
a? \square \text{let } x \leftarrow a? \text{ in } \delta &\asymp a? \\
a? \square \text{let } x \leftarrow a? \text{ in } \delta &\not\approx a?
\end{aligned}$$

As this example shows, mutual simulation does not have the power to detect deadlock, which is why Milner [19, exercise 14] chose to use bisimulation rather than mutual simulation for CCS.

In earlier versions of this paper, it was necessary to use mutual simulation rather than bisimulation, because I was unable to find a proof that bisimulation was a congruence for

Define may-testing for CMML Σ as $\Gamma \models e \sqsubseteq_o f : \tau$ iff $C[e] \xrightarrow{\sqrt{*}} *$ implies $C[f] \xrightarrow{\sqrt{*}}$ for any closing context C of type CI .

4 Bisimulation

We can define a notion of higher-order late bisimulation for CMML Σ , based on Abramsky's [2] applicative simulation for the untyped λ -calculus, Milner, Parrow and Walker's [20] late bisimulation for the π -calculus, and Howe's [13] simulation for lazy computation.

A (higher-order late) simulation on CMML Σ is a type-indexed family of relations $\mathcal{R}_\tau \subseteq \{(e, f) \mid \vdash e, f : \tau\}$ such that:

- if $e \mathcal{R}_{[A]} f$ then $e = f$.
- if $(e, e') \mathcal{R}_{\sigma \otimes \tau}(f, f')$ then $e \mathcal{R}_\sigma f$ and $e' \mathcal{R}_\tau f'$,
- if $(\lambda x. e) \mathcal{R}_{\sigma \rightarrow \text{CT}}(\lambda y. f)$ then for all $\vec{g} : \sigma$ we have

CMML Σ . However, Andy Pitts has since shown me an unpublished proof of Howe's [12] which can be adapted to show that bisimulation is a congruence for CMML Σ .

The full paper uses Gordon's variant [8] of Howe's proof technique [13, 12] to show that bisimulation is a congruence for CMML Σ .

Let CMML Σ be the signature with types as sorts, and judgements $\vec{x} : \vec{\sigma} \vdash e : \tau$ as constructors $\vec{\sigma} \rightarrow \tau$, viewed up to bisimulation. Any signature morphism $f : \Sigma \rightarrow \Sigma'$ extends homomorphically to a signature morphism CMML $f : \text{CMML}\Sigma \rightarrow \text{CMML}\Sigma'$, and it is routine to show that CMML : **SigBCD** \rightarrow **SigBCD** is a functor.

The equations in Table 3 include Moggi's equations for the monadic metalanguage, and so we can show that CMML Σ has categorical structure given by Table 4.

Proposition 1 *CMML Σ forms a category with finite products, a monad $T : \text{CMML}\Sigma \rightarrow \text{CMML}\Sigma$, and all T -exponentials.*

Proof The equations in Table 3 are sufficient to show that the structure defined in Table 4 has the required properties. This is shown in [22] and the full version of this paper. \square

5 Denotational semantics

Let **Alg** be the category of algebraic dcpo's, together with continuous morphisms (we are not requiring dcpo's to have least elements). Let **Alg** $_{\perp V}$ be the category of algebraic dcpo's with all finite joins, together with continuous morphisms which respect the joins. Let $X \rightarrow Y$ be the continuous function space between X and Y , and let $X \rightarrow_V Y$ be the continuous \vee -respecting function space between X and Y .

For any indexing sets J and K and for any object (\vec{I}, \vec{O}, V) in **Alg** $^{\text{op}J} \times \text{Alg}^K \times \text{Alg}$, a *pre-process domain* over (\vec{I}, \vec{O}, V) is an object P in **Alg** $_{\perp V}$ with morphisms:

$$\begin{aligned} \text{in}_j c &: (I_j \rightarrow P) \rightarrow_V P \\ \text{out}_k c &: O_k \rightarrow P \rightarrow_V P \\ \text{val} &: V \rightarrow P \rightarrow_V P \end{aligned}$$

for each $c \in \llbracket \text{chan} \rrbracket$, $j \in J$ and $k \in K$. A pre-process domain morphism is an **Alg** $_{\perp V}$ morphism which respects $\text{in}_j c$, $\text{out}_k c$ and val . A *process domain* is a pre-process domain where:

$$\begin{aligned} \text{in}_j c(f; \text{val } v) &\leq \text{val } v(\text{in}_j c f) \\ \text{out}_k c d(\text{val } v p) &\leq \text{val } v(\text{out}_k c d p) \\ \text{val } v(\text{val } w p) &= \text{val } w p \end{aligned} \quad (1)$$

Let $\text{Proc}(\vec{I}, \vec{O}, V)$ be the initial process domain over (\vec{I}, \vec{O}, V) .

Proposition 2 *Proc is a continuous and locally continuous functor **Alg** \rightarrow **Alg**.*

Proof Given in the full version of this paper. \square

Hennessy [10] has proposed a domain for higher-order processes which is the canonical fixed point of the functor:

$$X \mapsto \prod_c (X \rightarrow X)_{\perp} \times \prod_c (X \otimes_r X)$$

where \otimes_r is the left adjoint to \rightarrow_V :

$$\text{curry}_r : \mathbf{Alg}_V[X \otimes_r Y, Z] \simeq \mathbf{Alg}[X, Y \rightarrow_V Z]$$

We can extend this to typed processes by defining $\text{PreProc}(\vec{I}, \vec{O}, V)$ to be the canonical fixed point of the functor:

$$X \mapsto \prod_{j,c} (I_j \rightarrow X)_{\perp} \times \prod_{k,c} (O_k \otimes_r X)_{\perp} \times (V \otimes X)_{\perp}$$

Proposition 3

1. $\text{PreProc}(\vec{I}, \vec{O}, V)$ is the initial pre-process domain.
2. $\text{Proc}(\vec{I}, \vec{O}, V)$ is $\text{PreProc}(\vec{I}, \vec{O}, V)$ quotiented by the process domain preorder (1).

Proof Given in the full version of this paper. \square

Define the *traces* $\text{Trace}(\vec{I}, \vec{O}, V) \subseteq \text{Proc}(\vec{I}, \vec{O}, V)$ as the elements given by the grammar:

$$\begin{aligned} s &::= \perp \mid \text{in}_j c(d \Rightarrow s) \mid \text{out}_k c d s \mid \text{val } v u \\ u &::= \perp \mid \text{in}_j c(d \Rightarrow u) \mid \text{out}_k c d u \end{aligned}$$

for compact d and v .

Proposition 4 *p is compact iff $p = s_1 \vee \dots \vee s_n$ for traces s_i .*

Proof 'If' follows from showing by induction on s that s is compact. 'Only if' follows by showing that any p is the join of all the traces below it. \square

Any continuous function is determined by its effect on compact elements, and so we can define functions $\text{Proc}(\vec{I}, \vec{O}, V) \rightarrow_{\perp V} D$ by giving their effect on traces. For example, the restriction operator:

$$_ \upharpoonright _ : \text{Proc}(\vec{I}, \vec{O}, V) \rightarrow_{\perp V} \llbracket \text{chan} \rrbracket^n \rightarrow \text{Proc}(\vec{I}, \vec{O}, V)$$

is defined by its action on traces:

$$\begin{aligned} (\text{in}_j c(d \Rightarrow s)) \upharpoonright \vec{c} &= \begin{cases} \text{in}_j c(d \Rightarrow (s \upharpoonright \vec{c})) & \text{if } c \in \vec{c} \\ \perp & \text{otherwise} \end{cases} \\ (\text{out}_k c d s) \upharpoonright \vec{c} &= \begin{cases} (\text{out}_k c d (s \upharpoonright \vec{c})) & \text{if } c \in \vec{c} \\ \perp & \text{otherwise} \end{cases} \\ (\text{val } v u) \upharpoonright \vec{c} &= \text{val } v(u \upharpoonright \vec{c}) \end{aligned}$$

We can define concurrency, and the monad natural transformations similarly:

$$\begin{aligned} _ \parallel _ &: \text{Proc}(\vec{I}, \vec{O}, V) \rightarrow_V \text{Proc}(\vec{I}, \vec{O}, W) \rightarrow_V \text{Proc}(\vec{I}, \vec{O}, W) \\ _ * _ &: (V \rightarrow W) \rightarrow \text{Proc}(\vec{I}, \vec{O}, V) \rightarrow_{\perp V} \text{Proc}(\vec{I}, \vec{O}, W) \\ \mu &: \text{Proc}(\vec{D}, \vec{D}, \text{Proc}(\vec{D}, \vec{D}, V)) \rightarrow_{\perp V} \text{Proc}(\vec{D}, \vec{D}, V) \\ \eta &: V \rightarrow \text{Proc}(\vec{I}, \vec{O}, V) \end{aligned}$$

$$\begin{aligned}
x &\approx^\circ * \\
(v.L, v.R) &\approx^\circ v \\
\text{let } x \leftarrow [e] \text{ in } f &\approx^\circ f[e/x] \\
\text{let } x \leftarrow e \text{ in } [x] &\approx^\circ e \\
\text{let } y \leftarrow (\text{let } x \leftarrow e \text{ in } f) \text{ in } g &\approx^\circ \text{let } x \leftarrow e \text{ in } (\text{let } y \leftarrow f \text{ in } g) \\
(\lambda x. e). f &\approx^\circ e[f/x] \\
\lambda y. (gy) &\approx^\circ g
\end{aligned}$$

Table 3: Some bisimulations for CMML Σ (y not free in g)

$$\begin{aligned}
\text{id}_\tau &= (x : \tau \vdash x : \tau) \\
(x : \rho \vdash e : \sigma); (y : \sigma \vdash f : \tau) &= (x : \rho \vdash f[e/x] : \tau) \\
1 &= I \\
!_\tau &= (x : \tau \vdash * : I) \\
\sigma \times \tau &= \sigma \otimes \tau \\
\pi &= (x : \sigma \otimes \tau \vdash x.L : \sigma) \\
\pi' &= (x : \sigma \otimes \tau \vdash x.R : \tau) \\
T\tau &= C\tau \\
T(x : \sigma \vdash e : \tau) &= (y : C\sigma \vdash \text{let } x = y \text{ in } [e] : C\tau) \\
\eta_\tau &= (x : \tau \vdash [x] : C\tau) \\
\mu_\tau &= (x : CC\tau \vdash \text{let } y \leftarrow x \text{ in } y : C\tau) \\
t_{\sigma, \tau} &= (x : \sigma \otimes C\tau \vdash \text{let } y \leftarrow x.R \text{ in } [(x.L, y)] : C(\sigma \otimes \tau)) \\
T\tau^\sigma &= \sigma \rightarrow C\tau \\
\text{curry}(x : \rho \otimes \sigma \vdash e : C\tau) &= (y : \rho \vdash \lambda z. \text{let } x \leftarrow [(y, z)] \text{ in } e : \sigma \rightarrow C\tau) \\
\text{curry}^{-1}(x : \rho \vdash e : \sigma \rightarrow C\tau) &= (y : \rho \otimes \sigma \vdash e(y.R) : C\tau)
\end{aligned}$$

Table 4: Categorical structure of CMML Σ

Proposition 5 $\text{Proc}(\vec{D}, \vec{D}, _)$: $\mathbf{Alg} \rightarrow \mathbf{Alg}$ is a monad.

Proof Given in the full version of this paper. \square

Given a semantics $\llbracket _ \rrbracket : \Sigma \rightarrow \mathbf{Alg}$ for Σ , we extend it to CMML Σ by giving the an object $\llbracket \tau \rrbracket$ in \mathbf{Alg} for each type τ :

$$\begin{aligned}
\llbracket I \rrbracket &= 1 \\
\llbracket \sigma \otimes \tau \rrbracket &= \llbracket \sigma \rrbracket \times \llbracket \tau \rrbracket \\
\llbracket \sigma \rightarrow C\tau \rrbracket &= \llbracket \sigma \rrbracket \rightarrow \llbracket C\tau \rrbracket \\
\llbracket C\tau \rrbracket &\simeq \text{Proc}(\langle \llbracket \sigma \rrbracket \mid \sigma \in \mathbf{T} \rangle, \langle \llbracket \sigma \rrbracket \mid \sigma \in \mathbf{T} \rangle, \llbracket \tau \rrbracket)
\end{aligned}$$

where \mathbf{T} is the set of all CMML types, and for each $\vec{x} : \vec{\sigma} \vdash e : \tau$ a morphism:

$$\llbracket x_1 : \sigma_1, \dots, x_n : \sigma_n \vdash e : \tau \rrbracket : \llbracket \sigma_1 \rrbracket \times \dots \times \llbracket \sigma_n \rrbracket \rightarrow \llbracket \tau \rrbracket$$

given by:

- $\llbracket * \rrbracket$ and $\llbracket (e, f) \rrbracket$ are given by the products in \mathbf{Alg} ,
- $\llbracket [e] \rrbracket$ and $\llbracket \text{let } x \leftarrow e \text{ in } f \rrbracket$ are given by the monadic structure of Proc ,
- $\llbracket \lambda x. e \rrbracket$ and $\llbracket ef \rrbracket$ are given by the Proc -exponentials in \mathbf{Alg} ,
- $\llbracket \text{if } e \text{ then } f \text{ else } g \rrbracket$ is given by the coproducts in \mathbf{Alg} ,
- $\llbracket \delta \rrbracket$ and $\llbracket [e \square f] \rrbracket$ are given by bottom and join in $\text{Proc}[\llbracket \tau \rrbracket]$,
- $\llbracket \text{fix}(x = e) \rrbracket$ is the least fixed point of $x \mapsto \llbracket e \rrbracket$, and
- $\llbracket [e?] \rrbracket$, $\llbracket [e!f] \rrbracket$, $\llbracket [e \parallel f] \rrbracket$ and $\llbracket [e \downarrow f] \rrbracket$ are given as above.

This semantics is defined in full in the full version of the paper.

We shall sometimes elide the type information, and write $\llbracket e \rrbracket$ for $\llbracket \Gamma \vdash e : \tau \rrbracket$ where this is unambiguous.

A semantics $\llbracket _ \rrbracket : \Sigma \rightarrow \mathbf{Alg}$ is adequate iff:

$$\llbracket \vdash d\vec{e} : C[A] \rrbracket = \bigvee \{ \llbracket \vdash [f] : C[A] \rrbracket \mid d\vec{e} \xrightarrow{\! \! \! \!} f \}$$

A semantics $\llbracket _ \rrbracket : \Sigma \rightarrow \mathbf{Alg}$ is *expressive* iff for any compact $a \in \llbracket A \rrbracket$ we can find terms is_a and $test_a$ such that:

$$\llbracket \vdash is_a : [A] \rrbracket = a \quad \llbracket \vdash test_a : [A] \rightarrow CI \rrbracket = (a \Rightarrow \eta \perp)$$

A semantics $\llbracket _ \rrbracket : \text{CMML}\Sigma \rightarrow \mathbf{Alg}$ is *correct* iff:

$$\llbracket \Gamma \vdash e : \tau \rrbracket \leq \llbracket \Gamma \vdash f : \tau \rrbracket \text{ implies } \Gamma \models e \sqsubseteq_O f : \tau$$

The semantics for $\text{CMML}\Sigma$ is *fully abstract* iff:

$$\llbracket \Gamma \vdash e : \tau \rrbracket \leq \llbracket \Gamma \vdash f : \tau \rrbracket \text{ iff } \Gamma \models e \sqsubseteq_O f : \tau$$

We will now sketch the proof that if a semantics for Σ is adequate then its extension to $\text{CMML}\Sigma$ is correct, and that if a semantics for Σ is adequate and expressive, then its extension to $\text{CMML}\Sigma$ is fully abstract.

6 Program logic

In order to show the relationship between the operational and denotational semantics of $\text{CMML}\Sigma$, we shall use a *program logic* similar to that used by Abramsky [2] and Ong [23] in modelling the untyped λ -calculus, based on Abramsky's [3] *domain theory in logical form*.

The *program logic* for $\text{CMML}\Sigma$ has propositions:

$$\phi ::= * \mid (\phi, \psi) \mid |a| \mid \omega \mid \phi \wedge \psi \mid \phi \Rightarrow \psi \mid \langle c?_{\sigma} \rangle \phi \mid \langle c!_{\sigma} \rangle \phi \mid \langle \surd \rangle \phi$$

These can be statically typed, so the propositions for type τ are those where $\phi : \mathcal{L}\tau$, given by the type system in Table 5.

The operational characterization of the logic has judgements $\models e : \phi$ given for closed terms by Table 6. This can be generalized to open terms as:

$$\vec{x} : \vec{\phi} \models e : \psi \text{ iff } \forall \vec{f} : \vec{\phi}. \models e[\vec{f}/\vec{x}] : \psi$$

Let Δ range over propositional contexts of the form $x_1 : \phi_1, \dots, x_n : \phi_n$, and write $\Delta : \mathcal{L}\Gamma$ for:

$$(x_1 : \phi_1, \dots, x_n : \phi_n) : \mathcal{L}(x_1 : \tau_1, \dots, x_n : \tau_n) \\ \text{iff } \phi_1 : \mathcal{L}\tau_1, \dots, \phi_n : \mathcal{L}\tau_n$$

We can also define a denotational semantics for propositions, so that if $\phi : \mathcal{L}\tau$ then $\llbracket \phi \rrbracket \in \llbracket \tau \rrbracket$:

$$\begin{aligned} \llbracket * \rrbracket &= \perp & \llbracket (\phi, \psi) \rrbracket &= (\llbracket \phi \rrbracket, \llbracket \psi \rrbracket) \\ \llbracket \omega \rrbracket &= \perp & \llbracket \phi \wedge \psi \rrbracket &= \llbracket \phi \rrbracket \vee \llbracket \psi \rrbracket \\ \llbracket |a| \rrbracket &= a & \llbracket \phi \Rightarrow \psi \rrbracket &= \llbracket \phi \rrbracket \Rightarrow \llbracket \psi \rrbracket \\ \llbracket \langle c?_{\sigma} \rangle \phi \rrbracket &= \text{inc} \llbracket \phi \rrbracket & \llbracket \langle c!_{\sigma} \rangle (\phi, \psi) \rrbracket &= \text{outc} \llbracket \phi \rrbracket \llbracket \psi \rrbracket \\ \llbracket \langle \surd \rangle (\phi, \psi) \rrbracket &= \text{val} \llbracket \phi \rrbracket \llbracket \psi \rrbracket \end{aligned}$$

Whenever $\Delta : \mathcal{L}\Gamma$, we can define $\llbracket \Delta \rrbracket \in \llbracket \Gamma \rrbracket$ as:

$$\llbracket x_1 : \phi_1, \dots, x_n : \phi_n \rrbracket = (\llbracket \phi_1 \rrbracket, \dots, \llbracket \phi_n \rrbracket)$$

Proposition 6 $a \in \llbracket \tau \rrbracket$ is compact iff $\exists \phi : \mathcal{L}\tau. a = \llbracket \phi \rrbracket$.

Proof 'If' is an induction on ϕ . 'Only if' relies on Proposition 4. \square

7 Full abstraction

We can now show that the semantics for $\text{CMML}\Sigma$ is fully abstract. We begin by showing that if Σ is expressive, then so is $\text{CMML}\Sigma$.

The *primes* of the logic are given by:

$$\begin{aligned} \pi &::= \omega \mid \langle c?_{\tau} \rangle (\phi \Rightarrow \pi) \mid \langle c!_{\tau} \rangle (\phi, \pi) \mid \langle \surd \rangle (\phi, \nu) \\ \nu &::= \omega \mid \langle c?_{\tau} \rangle (\phi \Rightarrow \nu) \mid \langle c!_{\tau} \rangle (\phi, \nu) \end{aligned}$$

Note that $\llbracket \pi \rrbracket$ is a trace, and so by Proposition 4 for any $\phi \in \mathcal{L}(C\tau)$ we can find π_i such that $\phi = \pi_1 \wedge \dots \wedge \pi_n$.

Proposition 7 *If the semantics for Σ is expressive, then for any $\phi : \mathcal{L}\tau$ we can find a term $\vdash \text{term } \phi : \tau$ such that $\llbracket \phi \rrbracket = \llbracket \text{term } \phi \rrbracket$.*

Proof Let $\text{term}_{\tau} \phi$ be defined as in Table 7, where result is an unused channel, and when $\pi \in \mathcal{L}(C\tau)$ then $\bar{\pi} \in \mathcal{L}(CI)$ is:

$$\begin{aligned} \bar{\omega} &= [*] \\ \overline{\langle c?_{\sigma} \rangle (\phi \Rightarrow \pi)} &= \langle c!_{\sigma} \rangle (\phi, \bar{\pi}) \\ \overline{\langle c!_{\sigma} \rangle (\phi, \pi)} &= \langle c?_{\sigma} \rangle (\phi \Rightarrow \bar{\pi}) \\ \overline{\langle \surd \rangle (\phi, \nu)} &= \langle \text{result?}_{\tau} \rangle (\phi \Rightarrow \bar{\nu}) \end{aligned}$$

Then show by induction on ϕ that $\llbracket \text{term } \phi \rrbracket = \llbracket \phi \rrbracket$. \square

We can then verify that: $\llbracket \phi \rrbracket = \llbracket \vdash \text{term}_{\tau} \phi : \tau \rrbracket$ This expressivity result is used in showing that the semantics for $\text{CMML}\Sigma$ is fully abstract. The relationship between expressivity and full abstraction has been long known [17, 25].

Proposition 8

1. If a semantics for Σ is adequate, then $\llbracket \phi \rrbracket \leq \llbracket e \rrbracket \llbracket \Delta \rrbracket$ implies $\Delta \models e : \phi$.
2. If a semantics for Σ is expressive and adequate, then $\llbracket \phi \rrbracket \leq \llbracket e \rrbracket \llbracket \Delta \rrbracket$ iff $\Delta \models e : \phi$.

Proof The first part of this proof is a straightforward correctness proof, and follows by induction on e .

The proof of the second part begins by showing by induction on ϕ that if $\models e : \phi$ then $\llbracket \phi \rrbracket \leq \llbracket e \rrbracket \perp$. This requires expressiveness, for example to prove the case when $\phi = \psi \Rightarrow \chi$ we reason:

$$\begin{aligned} \models \lambda x. e : \psi \Rightarrow \chi & \\ \Rightarrow \models (\lambda x. e)(\text{term } \psi) : \chi & \quad (\text{Expressiveness}) \\ \Rightarrow \llbracket \chi \rrbracket \leq \llbracket \lambda. e \rrbracket \llbracket \text{term } \psi \rrbracket & \quad (\text{Induction}) \\ \Rightarrow \llbracket \chi \rrbracket \leq \llbracket \lambda. e \rrbracket \llbracket \psi \rrbracket & \quad (\text{Expressiveness}) \\ \Rightarrow \llbracket \psi \Rightarrow \chi \rrbracket \leq \llbracket \lambda. e \rrbracket \perp & \quad (\text{Defn of } \Rightarrow) \end{aligned}$$

The result then follows. \square

We can combine these propositions to prove full abstraction for $\text{CMML}\Sigma$.

Theorem 9 (full abstraction)

1. If a semantics for Σ is adequate, then its extension to $\text{CMML}\Sigma$ is correct.

$$\begin{array}{c}
\frac{}{*: \mathcal{L}I} \quad \frac{\phi : \mathcal{L}\sigma \quad \psi : \mathcal{L}\tau}{(\phi, \psi) : \mathcal{L}(\sigma \otimes \tau)} \quad \frac{}{|a| : \mathcal{L}[A]} [a \in \llbracket A \rrbracket, a \text{ is compact}] \\
\frac{}{\omega : \mathcal{L}(\mathcal{C}\tau)} \quad \frac{\phi : \mathcal{L}(\mathcal{C}\tau) \quad \psi : \mathcal{L}(\mathcal{C}\tau)}{\phi \wedge \psi : \mathcal{L}(\mathcal{C}\tau)} \quad \frac{\phi : \mathcal{L}\tau}{[\phi] : \mathcal{L}(\mathcal{C}\tau)} \\
\frac{}{\omega : \mathcal{L}(\sigma \rightarrow \mathcal{C}\tau)} \quad \frac{\phi : \mathcal{L}(\sigma \rightarrow \mathcal{C}\tau) \quad \psi : \mathcal{L}(\sigma \rightarrow \mathcal{C}\tau)}{\phi \wedge \psi : \mathcal{L}(\sigma \rightarrow \mathcal{C}\tau)} \quad \frac{\phi : \mathcal{L}\sigma \quad \psi : \mathcal{L}(\mathcal{C}\tau)}{\phi \Rightarrow \psi : \mathcal{L}(\sigma \rightarrow \mathcal{C}\tau)} \\
\frac{c \in \llbracket \text{chan} \rrbracket \quad \phi : \mathcal{L}(\sigma \rightarrow \mathcal{C}\tau)}{\langle c?_{\sigma} \rangle \phi : \mathcal{L}(\mathcal{C}\tau)} \quad \frac{c \in \llbracket \text{chan} \rrbracket \quad \phi : \mathcal{L}(\sigma \otimes \mathcal{C}\tau)}{\langle c!_{\sigma} \rangle \phi : \mathcal{L}(\mathcal{C}\tau)} \quad \frac{\phi : \mathcal{L}(\tau \otimes \mathcal{C}\tau)}{\langle \surd \rangle \phi : \mathcal{L}(\mathcal{C}\tau)}
\end{array}$$

Table 5: The type system for the program logic

$$\begin{array}{c}
\frac{}{\models **} \quad \frac{\models e : \phi \quad \models f : \psi}{\models (e, f) : (\phi, \psi)} \quad \frac{a \leq \llbracket \vdash e : [A] \rrbracket}{\models e : |a|} \quad \frac{}{\models e : \omega} \quad \frac{\models e : \phi \quad \models e : \psi}{\models e : \phi \wedge \psi} \quad \frac{e \xrightarrow{\surd} e' \quad \models (f, e' \parallel [g]) : \phi}{\models e : \langle \surd \rangle \phi} \\
\frac{e \xrightarrow{\cdot} e' \quad \models e' : \phi}{\models e : \phi} \quad \frac{\forall \models f : \phi. \models ef : \psi}{\models e : \phi \Rightarrow \psi} \quad \frac{e \xrightarrow{c!_{\sigma} f} e' \quad \models (f, e') : \phi}{\models e : \langle c!_{\sigma} \rangle \phi} \quad \frac{e \xrightarrow{c?_{\sigma} x} e' \quad \models \lambda x. e' : \phi}{\models e : \langle c?_{\sigma} \rangle \phi}
\end{array}$$

Table 6: The operational characterization of the program logic

$$\begin{array}{l}
\text{term}_I * = * \\
\text{term}_{\sigma \otimes \tau}(\phi, \psi) = (\text{term}_{\sigma} \phi, \text{term}_{\tau} \psi) \\
\text{term}_{[A]} |a| = \text{is}_a \\
\text{term}_{\mathcal{C}\tau} \omega = \delta \\
\text{term}_{\mathcal{C}\tau}(\phi \wedge \psi) = \text{term}_{\mathcal{C}\tau} \phi \square \text{term}_{\mathcal{C}\tau} \psi \\
\text{term}_{\mathcal{C}\tau}[\phi] = [\text{term}_{\tau} \phi] \\
\text{term}_{\sigma \rightarrow \mathcal{C}\tau} \omega = \lambda x. \delta \\
\text{term}_{\sigma \rightarrow \mathcal{C}\tau}(\phi \wedge \psi) = \lambda x. (\text{term}_{\sigma \rightarrow \mathcal{C}\tau} \phi)x \square (\text{term}_{\sigma \rightarrow \mathcal{C}\tau} \psi)x \\
\text{term}_{I \rightarrow \mathcal{C}\tau}(* \Rightarrow \chi) = \lambda x. \text{term}_{\mathcal{C}\tau} \chi \\
\text{term}_{\rho \otimes \sigma \rightarrow \mathcal{C}\tau}((\psi, \phi) \Rightarrow \chi) = \lambda x. \text{let } y \leftarrow (\text{term}_{\rho \rightarrow \mathcal{C}I}(\psi \Rightarrow [*]))(x.L) \\
\quad \text{in } (\text{term}_{\sigma \rightarrow \mathcal{C}\tau}(\phi \Rightarrow \chi))(x.R) \\
\text{term}_{[A] \rightarrow \mathcal{C}\tau}(|a| \Rightarrow \chi) = \lambda x. \text{let } y \leftarrow (\text{test}_a x) \text{ in } \text{term}_{\mathcal{C}\tau} \chi \\
\text{term}_{\sigma \rightarrow \mathcal{C}\tau}(\omega \Rightarrow \chi) = \lambda x. \text{term}_{\mathcal{C}\tau} \chi \\
\text{term}_{\sigma \rightarrow \mathcal{C}\tau}(\phi \wedge \psi \Rightarrow \chi) = \lambda x. \text{let } y \leftarrow \text{term}_{\sigma \rightarrow \mathcal{C}I}(\phi \Rightarrow [*])x \\
\quad \text{in } \text{term}_{\sigma \rightarrow \mathcal{C}\tau}(\psi \Rightarrow \chi)x \\
\text{term}_{\mathcal{C}\sigma \rightarrow \mathcal{C}\tau}([\phi] \Rightarrow \chi) = \lambda x. \text{let } y \leftarrow x \text{ in } \text{term}_{\sigma \rightarrow \mathcal{C}\tau} y \\
\text{term}_{(\rho \rightarrow \mathcal{C}\sigma) \rightarrow \mathcal{C}\tau}((\phi \Rightarrow \psi) \Rightarrow \chi) = \lambda x. (\text{term}_{\mathcal{C}\sigma \rightarrow \mathcal{C}\tau}(\psi \Rightarrow \chi))(x(\text{term}_{\rho} \phi))
\end{array}$$

Table 7: Expressiveness result for CMML

2. If a semantics for Σ is expressive and adequate then its extension to $\text{CMML}\Sigma$ is fully abstract.

Proof Follows from the results that:

- $\llbracket \tau \rrbracket$ is algebraic,
- the compact elements of $\llbracket \tau \rrbracket$ are characterized precisely as the denotations $\llbracket \phi \rrbracket$ of formulae of type $\phi : \mathcal{L}\tau$, and
- the operational and denotation characterizations of when a term satisfies a formula are equivalent \square

8 Conclusions

This paper has shown that it is possible to combine some of the categorical structure used in giving denotational semantics of functional programming languages with the operational view of programs used to model process algebras.

In the full paper, the monadic structure is shown to be exactly the structure required to give denotational models for a programming language with monadic types. There is also a translation of a subset of CML into CMML, based on Moggi's translation of the call-by-value λ -calculus into MML.

There are a number of outstanding issues for this language:

- Is there a fully abstract semantics for CMML with unique name generation? (This is the most important feature of CML or CHOCS missing from CMML.)
- Is there a fully abstract semantics for must-testing [9] based on acceptance trees [9] or failures sets [11]?

Acknowledgements

This work is funded by SERC project GR/H 16537, and is carried out in the context of Esprit BRA 7166 Concur 2. Many thanks to Bill Ferreira, Andy Gordon, Matthew Hennessy, Andy Pitts and Edmund Robinson for discussions on this material.
